Do.

Do.

Your tasks and your meetings on one timeline, on a phone that opens.

Product	Do. - iOS, paid once
Price	USD 9.99 worldwide / EGP 99 in Egypt
Owner	Ahmed Hassaan
Status	Running on device, build 2026-11-10-1715
Date	10 November 2026 - revised after the calendar shipped

This plan is ordered by the risks that actually bite, not by the work that feels exciting. Section 2 is the one that can stop everything else.

SECTION ONE

Where the product actually is

Do. is not a prototype. It is a working app, installed and running on a folding iPhone today, built from a single HTML file wrapped in a native iOS shell. What follows is what exists, not what is planned.

What changed since the first draft of this plan

The first draft described a to-do app. In the day since, Do. became something harder to dismiss - and the change is large enough that it moves both the App Review risk in section two and the price argument in section five.

Added	What it is
A calendar	A sixth panel, and a real one: day and week views, a strip of the next seven days, the current-time line, tap an empty slot to create
Your actual meetings	Not only dated tasks - the real events from the real calendar accounts on the phone
Five widgets, up from three	And now on the LOCK SCREEN as well as the home screen: your next meeting, or your lists, under the clock

That turns the product from *a nicer Reminders* into the only place your tasks and your meetings sit on the same timeline - which is something neither Reminders nor Calendar does, because Apple ships them as two separate apps.

Working today

Capability	State	Evidence
Task lists, dates, notes, scheduled tasks	Done	Four lists, natural-language dates, 74 parser tests passing
Calendar: day and week, with the current-time line	Done	A sixth panel; tap an empty slot to create
Real meetings from the phone's own accounts	Done	EventKit, read-only; plus subscribed links, which work everywhere
Natural date entry	Done	'call mum tomorrow 6pm' sets the date itself
Works offline, no account needed	Done	All storage local; sync is opt-in
Local notifications	Done	Scheduled by iOS, fire with the app closed, verified on the lock screen
Widgets, home screen and lock screen	Done	Five WidgetKit widgets reading the app's own App Group storage
Folding layout	Done	Verified at eight widths by an automated harness
Installed on device	Done	Signed and running on iPhone19,4, iOS 27.3
App Store listing	Not started	Needs the work in sections 2 and 6

How the calendar gets real events

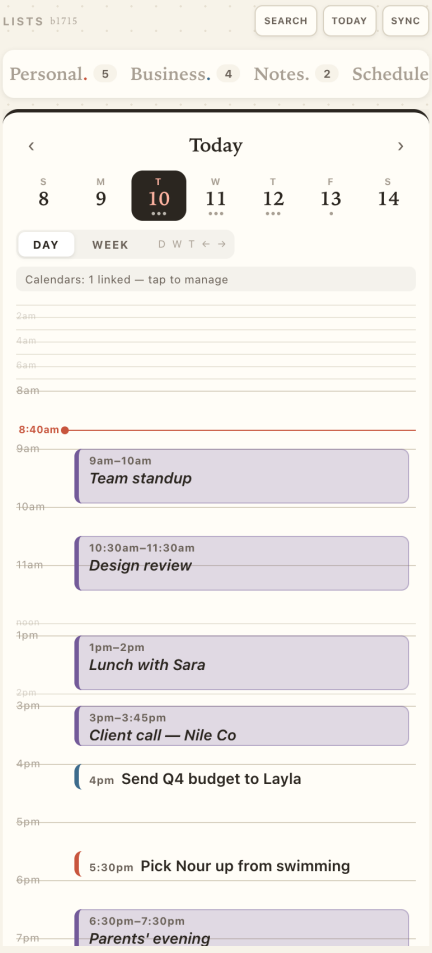

Three routes. The app uses whichever is available, in this order:

Route	Where it works	What it takes
A subscribed link (ICS)	Everywhere - Mac, web, phone	Paste a calendar's address once
EventKit	iPhone only	One permission prompt; then every account already set up on the phone - Outlook, iCloud, Gmail - arrives in a single list
Microsoft Graph	Built, not usable	Needs an Entra app registration and a company administrator's consent

EventKit is the one that matters, and it is worth understanding why it is such a good deal. On the web, every calendar provider is its own integration: a Microsoft app registration, a Google Cloud project, and nothing at all for iCloud, which has no public API. On the phone, iOS has already done that work - whatever accounts exist in Settings, EventKit hands over behind a single prompt. **This is a capability the web version structurally cannot have**, which makes it both a selling point and a Guideline 4.2 argument.

Read-only, deliberately

EventKit will delete an event as readily as it will read one, and deleting a meeting you organise sends cancellation emails to everyone on it. A to-do app that can do that by accident is a bad idea however carefully it is written. Writing is a decision to be made on purpose, not a capability to leave lying around.

The calendar on an iPhone. Meetings and tasks on one timeline; quiet hours compress so the day fits. Invented data.

Two bugs worth remembering

Both were silent, and both are the same shape - iOS accepting something and quietly substituting a placeholder rather than failing:

- **No Capacitor plugin was ever registered.** Capacitor 7 removed the Objective-C runtime scan that used to find plugins automatically. An unregistered plugin does not complain; it is simply absent. The widget bridge had never once worked. One line printing the list of registered plugins found it.
- **The lock-screen widgets showed 'Please adopt containerBackground'.** iOS 17 requires every widget family to declare a background; it had been applied only to the home-screen branch. Not a build error - WidgetKit swaps in the notice at render time, so it looked fine until it was on a real lock screen.

The lesson for a paid product: **the dangerous failures here are the quiet ones.** That is what the preflight and the error dot are for, and it is why anything new is looked at on real hardware before it is called done.

The engineering discipline already in place

This matters for a paid product, because it is what keeps a one-person app from breaking in public:

- **A preflight that blocks releases.** It refuses to stamp a build if the script will not compile, if ids are missing or duplicated, if the stylesheet is unbalanced, or if the build id disagrees across files.
- **A browser harness** checking layout containment, core flows and search at every width that matters.
- **74 date-parser tests and 11 ICS parser checks**, extracted from the shipping file by marker comment, so the tested code is always the shipped code.
- **An error dot** on the device: uncaught errors are recorded and shown, because the failure mode of this app is silence.

SECTION TWO

The gate: App Review, Guideline 4.2

This is the only thing in this document that can stop the whole plan. Everything else is a choice; this is a yes or no from Apple.

Do. is a bundled web layer in a native shell. Apple does not ban that. It rejects apps that are *no more than a repackaged website*, under Guideline 4.2, Minimum Functionality. A reviewer decides which one you are in about ninety seconds.

We currently look like a website in one visible place

The due date field is a raw web control:

```
<input type="datetime-local">
```

which is why the app shows **dd/mm/yyyy, --:--** instead of an iOS date picker. That grey web control, sitting in an otherwise carefully made screen, is precisely the signal reviewers are trained to look for: *web content that is not formatted for iOS*. It is also simply worse than the native control, so fixing it is not a compliance chore.

What counts in our favour

This risk has dropped materially since the first draft. The calendar and the lock-screen widgets are not decoration here: they are two capabilities a website cannot reach at all, which is the exact test a 4.2 reviewer applies.

In our favour	Why it matters
The web code is bundled, not fetched from a server	A locally bundled hybrid app is a different thing to a webview pointed at a URL
Real local notifications	Scheduled by iOS, fire offline with the app closed - a website cannot do this
EventKit calendar access	Reads the phone's real calendar accounts - a website cannot do this at all
Five WidgetKit widgets, including the lock screen	Accessory families under the clock; emphatically not web content
Genuine offline behaviour	No browser error page, no spinner, no login that forgets you

What I would add before submitting

Each of these is something a website cannot do, which is the actual test. Items 1 to 4 are the minimum I would submit on; 5 to 7 are what make it worth USD 9.99 rather than merely approvable.

#	Addition	Effort	Why
1	Native date and time picker	1 day	Removes the one visible flaw
2	App Intents and Siri	2 days	'Add buy milk to Personal'; also Shortcuts and the Action button
3	Spotlight indexing	1 day	Tasks findable from the iPhone home screen search
4	Share extension	1 day	Share a message or page, it becomes a task
5	Live Activity	2 days	A running scheduled task counting down in the Dynamic Island
6	Focus filters	1 day	Work Focus shows Business only

7	Native swipe actions and haptics	1 day	The list feels like a list, not a page

The deeper question, stated once

A web layer is a ceiling on how native this app can ever feel, and at USD 9.99 it competes with apps that are native to the bone. The alternative is rebuilding the interface in SwiftUI over the same model: weeks of work, and it throws away something that works beautifully today and deploys in sixty seconds. **My recommendation is not to do it yet.** Ship the hardened hybrid, find out whether people buy it, and let revenue rather than taste decide. But go in knowing the ceiling is there.

SECTION THREE

What you are actually selling

Not 'a to-do app'. There are thousands, and Apple gives Reminders away for nothing.

Two things now, and they reinforce each other.

> *One - the only to-do app designed on a folding iPhone from the first line of CSS.*

That claim is true, it is unusual, and - crucially - it is **visual**. It can be demonstrated in fifteen seconds without a word of explanation, which is what makes it marketable in a way that 'better task management' never is.

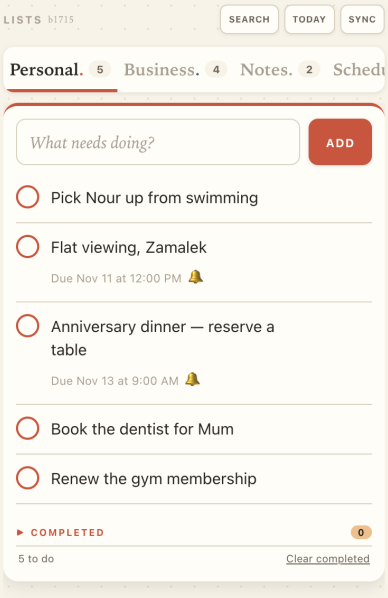

> *Two - the whole day in one place.*

Apple ships tasks and meetings as two separate apps and leaves you to hold both in your head. Do. puts them on one timeline: the 10:30 design review and 'send the budget by four' in the same column, in the order they will actually happen. The honest framing for the listing is not 'a to-do app with a calendar'. It is **the day you actually have, on a phone that opens.**

Measured on the actual device

State	Viewport	What the app does
Folded	373 x 603	One list; card fan to switch; the fan tucks away as you read
Unfolded	867 x 594	Three columns, side by side
Unfolded, wide	1114 x 594	Four columns including Scheduled tasks

No reload. No separate iPad build. No 'optimised for' asterisk. The layout is built on containment rather than pixel breakpoints, which is why it survives the hinge. It is verified at 320, 373, 430, 718, 900, 1114, 1280 and 1440 by a harness that runs on every change.

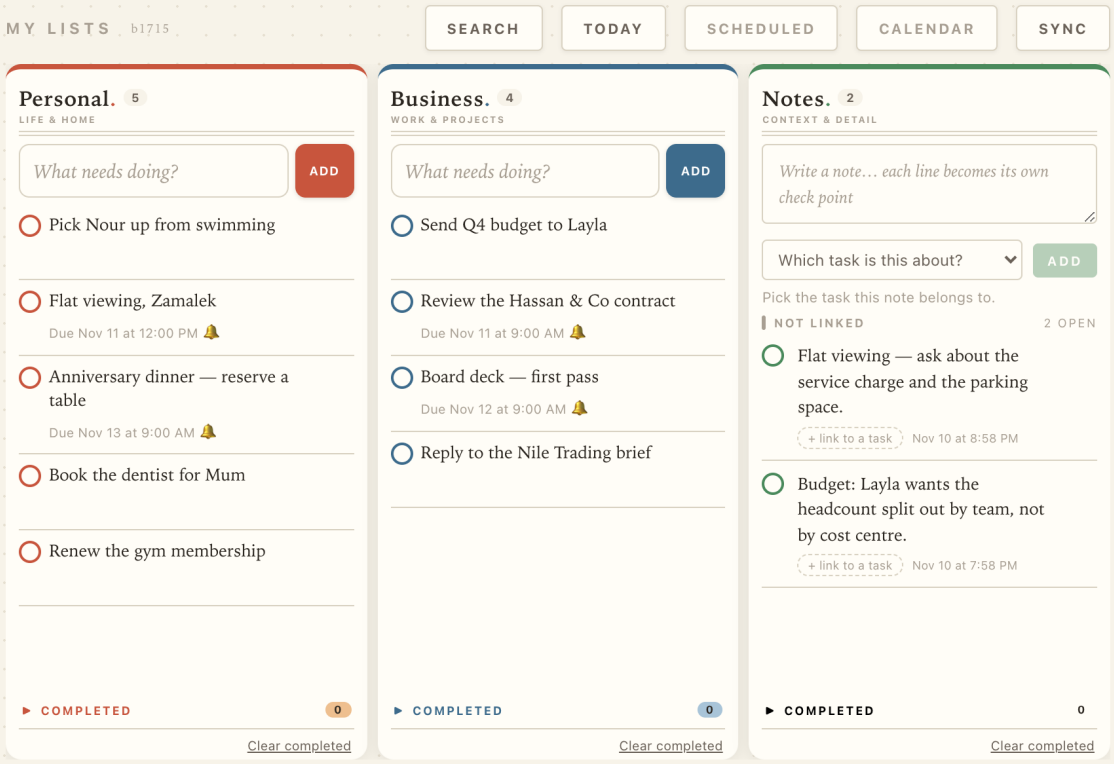

Folded, 373 x 603. One list, the card fan above it.

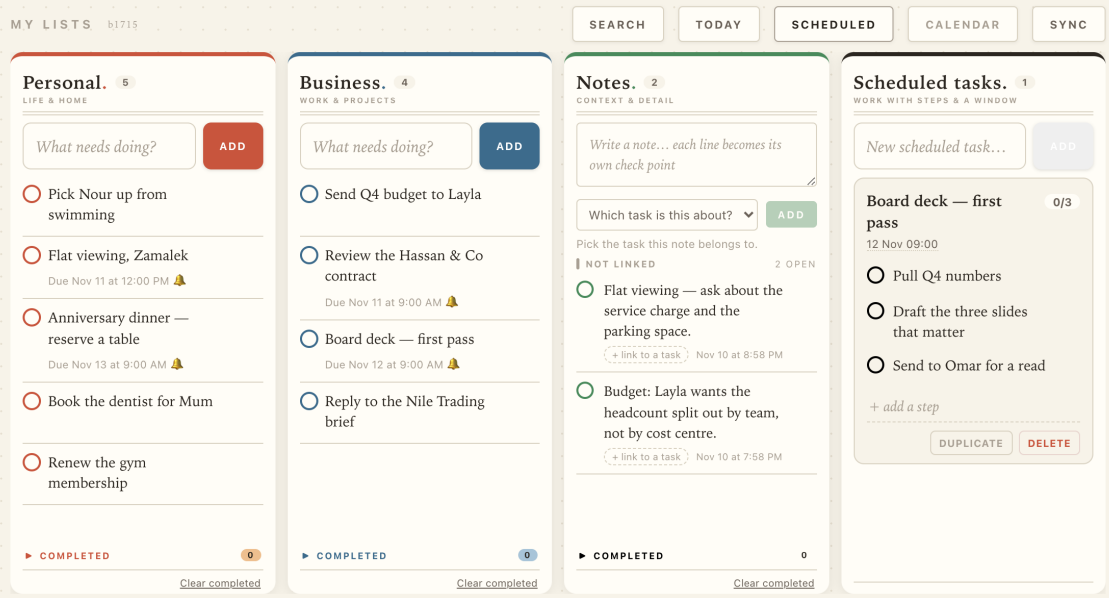

SECTION THREE, CONTINUED

The unfold

This is the campaign. Everything in section seven is about finding the most beautiful way to film the transition between these two pages.

Unfolded, 867 x 594. The same app, the same instant, three columns.

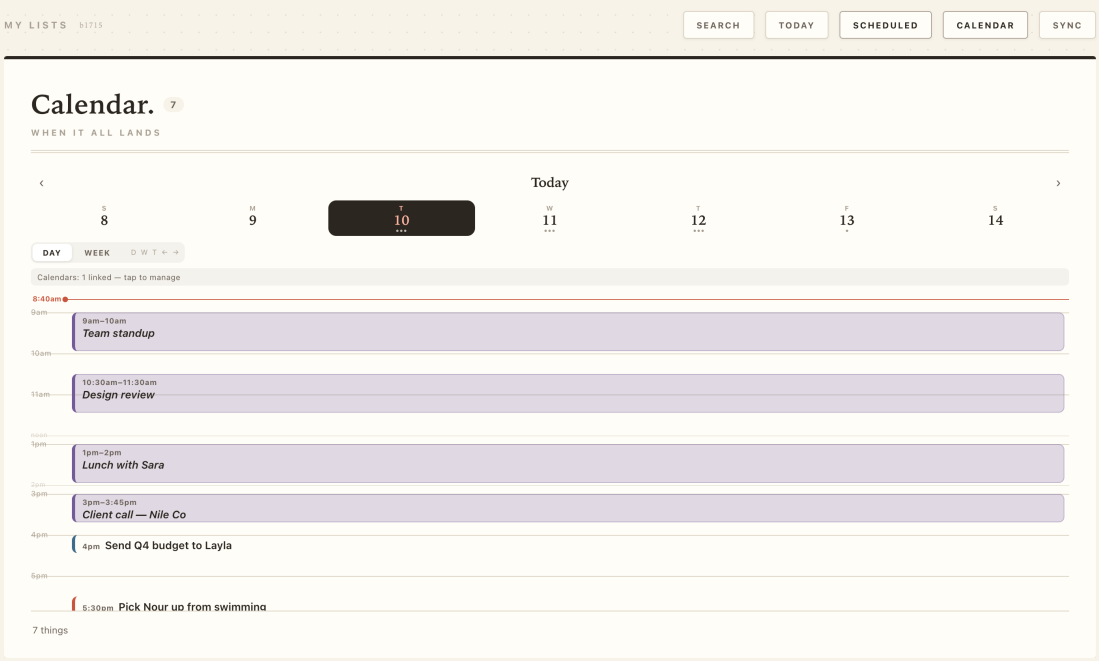

Unfolded wide, 1114 x 594. Scheduled tasks joins as a fourth column.

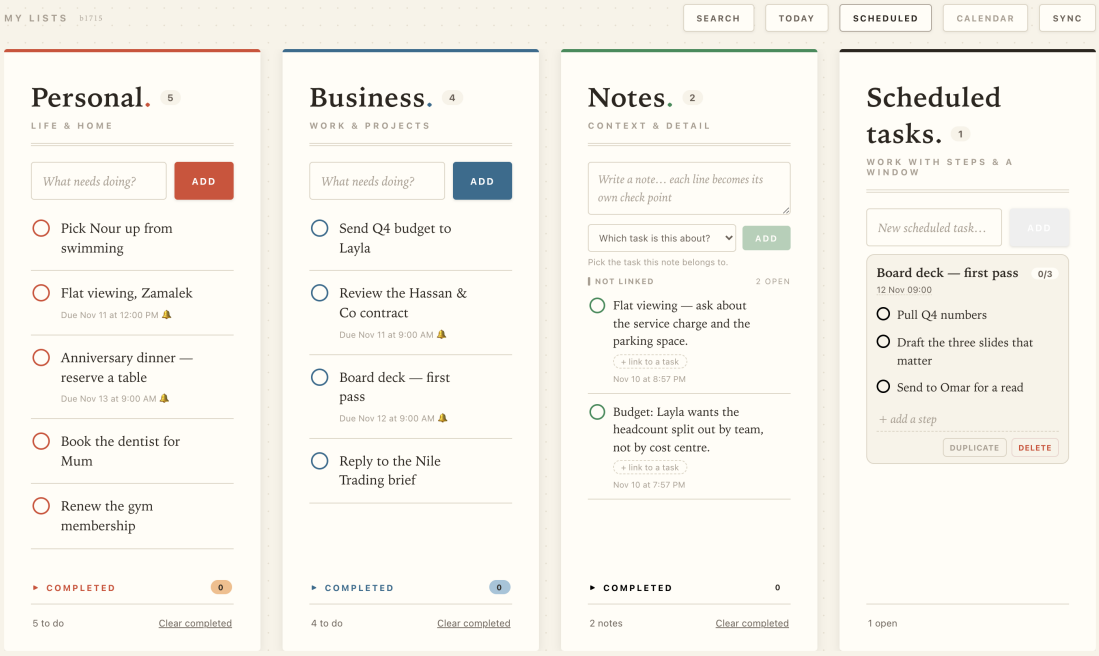

SECTION THREE, CONTINUED

The day in one place

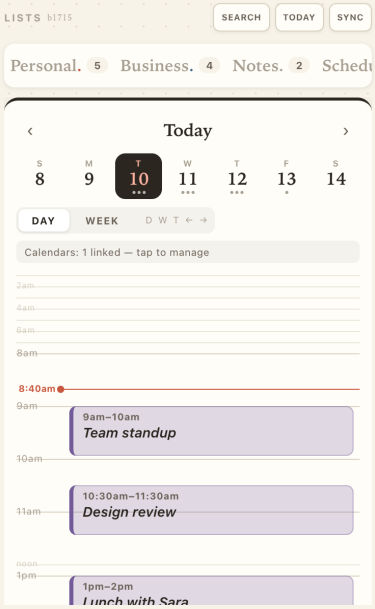

The same app on a Mac. Quiet hours compress to thin rules and the hours with something in them open up, so a whole day fits on one screen without the dead space an hour-by-hour grid forces on you. The purple blocks are meetings from a linked calendar; the thin coloured marks are tasks, in the same column, at the time they are due.

Mac, 1440 x 900. Every name, meeting and task in these pictures is invented.

The same window, lists view: four columns with room to breathe.

And folded, 373 x 603 - the same day, same elastic hours, on a screen a third the width.

SECTION FOUR

Name and brand

Do. - confirmed. The mark already exists and is already good: Iowan Old Style Bold on paper, a rust full stop, a rust bar across the top, a faint dotted grid behind. It reads as stationery rather than software, which is the whole personality.

Token	Value	Use
Paper	#f7f3e9	Every background, app and marketing
Rust	#c8553d	The full stop, the bar, primary actions
Ink	#2b2620	All body text
Ink soft	#6b6259	Secondary text
Serif	Iowan Old Style	The wordmark and all headings

Practical warnings on the name

- **'Do' alone is almost certainly taken on the App Store** and is close to unsearchable. The display name should carry a qualifier: *Do. - Lists that fold*, or similar. The icon and the wordmark stay 'Do.'
- Check availability in App Store Connect before anything is printed, filmed or registered. Reserving the name is free and takes minutes.
- Buy the domain at the same time, and the social handles, even if unused. This is the cheapest insurance in the plan.

SECTION FIVE

Price and what reaches you

Paid up front, one purchase, no subscription, no in-app purchases. It suits the product's character and it is what you asked for.

Enrol in the Small Business Program before the first sale

It is **not automatic**. It takes Apple's commission from 30% to 15% for developers under USD 1M a year, which is you. Forgetting costs you USD 1.50 on every single copy, forever.

	USD 9.99	EGP 99
Apple takes at 15% (Small Business Program)	1.50	15
You receive	8.49	84
Apple takes at 30% (if you forget to enrol)	3.00	30
You receive	6.99	69

Figures before local taxes, which Apple collects and remits.

Regional pricing is supported

Apple lets you set a base price and override it per storefront, so USD 9.99 worldwide with EGP 99 in Egypt is an ordinary configuration, not a workaround. **Unverified:** I could not confirm Apple's exact EGP price points from here - 99 may have to round to the nearest available point. Check the price grid in App Store Connect.

The honest risk on price

USD 9.99 once, against a free and pre-installed Reminders app, is a hard sell on features alone. It works for the premium apps in this category because their craft is undeniable in the first three seconds. That is the bar - and it is the strongest argument for doing section two properly rather than minimally. One-time pricing also means no recurring revenue to fund years of iOS updates; that is a real trade you are choosing deliberately.

What it takes to break even

Year one cost to recover	Copies at USD 8.49 net	Or copies at EGP 84 net
USD 99 (minimum: Apple only)	12	~60
USD 128 (Apple + domain)	16	~78
USD 428 (with a freelance editor for the film)	51	~250

EGP conversions are indicative only and move with the exchange rate.

SECTION SIX

Where it is hosted, and what that costs

There are four separate things people mean by 'hosting' here, and they have very different answers.

1. The app itself - nothing to host

Apple hosts and delivers the binary. There is no server, no bandwidth bill, no scaling problem, however many copies sell. This is the whole point of selling through the App Store and it is already paid for by the USD 99 membership.

2. The marketing site - free

Option	Cost	Notes
GitHub Pages	Free	Already in use for the web app; custom domains and HTTPS included
Cloudflare Pages	Free	Faster globally, better in Egypt, free tier is generous
Netlify / Vercel	Free tier	More than needed for a one-page site

Recommendation: Cloudflare Pages for the marketing site, because its edge network is noticeably better in the Middle East than GitHub's, and the free tier covers everything a landing page and a privacy policy will ever need.

3. Sync - and this is the important decision

The app works entirely offline and needs no backend at all. Sync is optional. But if you want it across devices, the choice matters more than it looks:

Option	Cost	Reality
Apple CloudKit	Free	Private data counts against each user's own iCloud quota, not yours. No server, no ops, no bill that grows with success. iOS only.
Supabase free tier	Free	500 MB database, 2 projects - but free projects PAUSE after 7 days idle. Unacceptable for a paid app.
Supabase Pro	USD 25/mo	USD 300/yr. Needed the moment you have real users on the current design. Next tier up is a cliff at USD 599/mo.

Recommendation: move sync to CloudKit. For an iOS-only paid app this is close to a free lunch - Apple carries the storage against each user's own iCloud allowance, there is no server for you to run, and the privacy story becomes genuinely excellent: your data never touches a machine the developer controls. It also removes a USD 300/year fixed cost and a scaling risk. The work is roughly three to four days.

Keep the existing Supabase path alive for the web version, which CloudKit cannot serve.

4. Domain, email, video, analytics

Item	Cost per year	Notes
Domain (.com)	USD 10 - 15	Buy early; cheapest insurance in this plan
Domain (.app)	USD 14 - 20	HTTPS enforced by the registry, which suits us
Email on the domain	Free	Cloudflare Email Routing forwards to your existing inbox
Video hosting	Free	YouTube and Vimeo free tiers; App Store previews are hosted by Apple
Analytics	Free, or ~USD 108	None is a legitimate choice and fits the privacy story. Plausible is ~USD 9/mo if you want it

SECTION SEVEN

The whole cost, year one

Three honest scenarios. The difference between them is almost entirely how much of the video work you buy rather than do.

Item	Lean	Sensible	Full
Apple Developer Program	99	99	99
Domain	0	14	14
Marketing site hosting	0	0	0
Sync (CloudKit)	0	0	0
Email on domain	0	0	0
Video editor (freelance, the hero film)	0	300	800
Music licence	0	0	60
Analytics	0	0	108
Paid launch promotion	0	0	300
TOTAL, year one (USD)	99	413	1,381
Copies to break even, at USD 8.49 net	12	49	163

If you keep sync on Supabase Pro instead of moving to CloudKit, add USD 300 a year to every column, and 36 more copies to break even.

What recurs after year one

Recurring	Amount
Apple Developer Program	USD 99 / year
Domain	USD 10 - 20 / year
Everything else at the lean tier	USD 0

The floor is USD 99 a year. That is the honest answer to 'what does it cost to run': twelve copies sold pays for the year, and everything after that is yours. This is an unusually cheap product to operate, because the app needs no server and the marketing site is static.

Not a cost, but a real budget: your time

The work in section eight is roughly three to four weeks of focused effort before submission. That is the actual investment. The money is almost a rounding error by comparison.

SECTION EIGHT

The plan, in order

First: the App Store is not the only way to share it

This matters because it decides what the beta looks like, and because one of the two routes costs nothing and works today.

Route	Who can get it	What it costs	What they do not get
The web link	Anyone, anywhere, today	Nothing	Widgets, lock screen, EventKit, reliable reminders
TestFlight	10,000 external testers via a public link	The USD 99 membership	Nothing - it is the real app
Free Apple ID (today)	Nobody, in practice	Nothing	7-day profiles; the device must be plugged into this Mac

TestFlight is more generous than people assume: a public link you can post anywhere, up to ten thousand testers, no device identifiers and no cables. The first build of each version gets a light Beta App Review, usually about a day; builds last 90 days. You can run a beta of ten thousand people without ever shipping a listing.

The two features the price rests on - the widgets and the lock screen - cannot be shown any way but TestFlight. That is the trigger to enrol.

The phases

Phase	Who	Time	What
0. Enrol	You	1-7 days	Apple Developer Program, ONE Apple ID. Enrol in the Small Business Program the same day. Reserve the app name.
1. Rename to Do.	Me	~1 hour	DO THIS FIRST. The app is still called 'My To Do List' on the home screen and in the widget gallery while everything inside says Do. Every screenshot and every frame of video will show that name.
2. Native hardening	Me	~1 week	Items 1-4 from section two, each behind the existing NATIVE guard so the web version is untouched.
3. The fold, deliberately	Me	~2 days	The layout already adapts; make it perform. Tune the transition, make state survive the hinge, test half-open. This is the footage.
4. Sync on CloudKit	Me	3-4 days	Removes the only recurring infrastructure cost and improves the privacy story. Optional for v1.
5. Beta	Both	~1 week	TestFlight, 10-20 people, at least three on folding hardware. Watch where they stop.
6. Store assets	Both	~3 days	Screenshots, preview videos, description, keywords, privacy label.
7. Submit	Me	1-3 days review	With review notes explaining the native surface explicitly.
8. Launch and film	Both	ongoing	Section nine.

Realistic first submission: four to six weeks from the day you enrol, assuming the app keeps working while we add to it - which is what the preflight and the harness are for.

The 7-day expiry dies on day one

A side effect worth naming: the moment we sign with the paid team, provisioning profiles go from 7 days to 365. The weekly reinstall you asked to be rid of disappears as soon as you enrol - before any of the rest of this plan happens.

SECTION NINE

The films

Three different things for three different places. Do not try to make one film do all three jobs.

A. The hero film - 60 to 75 seconds

For the site, X, LinkedIn, YouTube. One idea: *the app is the shape of your phone.*

#	Shot	Note
1	Black. A folded phone, screen off, on a paper-coloured surface.	Match #f7f3e9. The brand is a colour before it is a logo
2	A thumb wakes it. The LOCK SCREEN already says what is next.	The widget earns its place in the first five seconds
3	Open. One list. A task gets ticked.	Real hands, real speed. Never speed up the footage
4	Swipe to the calendar. The morning's meetings are already there.	The 'wait, it does that?' beat - and what justifies the price
5	Push the list up - the card fan tucks away, the list fills the phone.	The detail that says somebody thought about this
6	THE UNFOLD. One column becomes three.	ONE CONTINUOUS TAKE. A cut is what makes viewers assume you hid a reload
7	Fold it shut mid-task. Open again - exactly where you were.	Proof it is one app, not two
8	Home screen, the widget, the icon. Title card.	

Shot 6 is the whole film. Budget half your shooting time for it. Shot 4 is the one that changed since the last draft.

- **Voice:** none, or one line at the end. The typography is the brand. Let the screen talk.
- **Music:** a single piano or guitar motif, with one note landing exactly on the unfold.
- **Capture:** screen recording comes off the device over the cable - perfectly clean pixels, but no hands. The physical unfold needs a camera. So shoot both and composite: camera for the hinge, screen capture tracked onto the panel. This is the one job worth paying a freelance editor for.

B. App Store preview videos - up to three, 15 to 30 seconds

A different discipline: no hands, no voiceover, autoplay muted, and the first second has to land. Apple requires real device capture.

#	Subject	Length
1	The fold. Folded, unfolded, three columns. This is the one.	15s
2	The day. Meetings and tasks on one timeline, the week strip, tap an empty slot to add.	20s
3	It tells you. The lock screen widget, then a reminder arriving.	20s

C. Short form - 7 to 15 seconds

TikTok, Reels, Shorts. One idea each, hook in the first half second, caption burned in.

- *'Your to-do app wasn't made for this phone. Mine was.'* then the unfold.
- *'One list. Unfold. Three.'* Nothing else.

- *'My tasks and my meetings, same screen.'* The calendar, scrolling one day.
- *'I wrote this for myself in a single HTML file.'* then the unfold. The builder story - this is the one developers share.
- *'Watch what happens when I close it mid-task.'* Fold, open, still there.

Post the unfold on its own, repeatedly, with different captions. It is the only asset that needs no explanation.

SECTION TEN

The store listing

Element	Guidance
Name	'Do.' as the mark, with a qualifier for search: 'Do. - Lists that fold'. NOTE: the app is still literally named 'My To Do List' today. Rename before any asset is made. Check availability before printing anything.
Subtitle (30 chars)	The fold, or the speed. Not both.
Keywords	fold, folding, todo, tasks, calendar, agenda, reminders, widget, lock screen, offline, privacy
Screenshot 1	Three columns on the unfolded screen. It is the only screenshot in the category that looks like that, so it must be first.
Screenshot 2	The calendar: meetings and tasks on one timeline. This is the feature people pay for.
Screenshots 3-5	The lock screen widget under the clock, the folded list, natural date entry.
Description	First two lines are all most people read. Lead with the fold.
Privacy label	Still an advantage, but no longer trivial: the app now asks for calendar access. Declare calendar data as read on device, never transmitted, NOT linked to the user and NOT used for tracking - all true. Nothing else leaves the device unless sync is on; no account; no analytics.
Review notes	Explicitly list the native surface: notifications, widgets, App Intents, Spotlight, share extension. Make the reviewer's job easy.

Launch sequence

- **Before approval:** site live, film cut, handles registered, 20 beta testers briefed and ready to post on day one.
- **Day one:** the unfold clip everywhere at once. Product Hunt. Hacker News with the builder angle - 'I built my to-do app as one HTML file and wrapped it for the folding iPhone' is a title that gets read.
- **Week one:** reply to everything. Pitch the fold angle to iOS journalists and folding-phone reviewers; they need folding-specific software to write about and there is very little of it.
- **Egypt specifically:** the EGP 99 price is a genuine local story. Egyptian tech press and communities respond to a local developer shipping globally at a fair local price.

SECTION ELEVEN

Risks, and what I could not verify

Risk	Severity	What reduces it
Rejected under Guideline 4.2 as a repackaged website	Medium	Was High. EventKit and the lock-screen widgets are both things a website cannot do. Still needs section two, items 1-4, and explicit review notes
Calendar permission invites a reviewer's question	Medium	The answer is good - it shows your meetings beside your tasks - but it must be visibly true in the first screen after the prompt, or it reads as data collection
USD 9.99 does not convert against free Reminders	Medium	Craft in the first three seconds; the fold as a reason to look
One-time price funds no future development	Medium	Accepted deliberately. Revisit with a paid major version, not a subscription
Folding iPhone is a small market today	Medium	The app is excellent on ordinary iPhones too; the fold is the hook, not the product
A single HTML file is a ceiling on native feel	Medium	Revisit after launch, funded by revenue
Solo developer, no redundancy	Medium	The preflight, harness and tests exist precisely for this

Stated plainly, so nobody builds on sand

- **Apple's exact EGP price points.** Per-storefront pricing exists; whether exactly 99 is selectable I could not confirm. Check App Store Connect.
- **The folding iPhone's official name and specifications.** Every search result was rumour-grade and they contradicted each other. Use Apple's own name for the device in all copy. The screen numbers in section three come from the device in your hand, which is better evidence than any article.
- **CloudKit's current free limits for public data.** Apple no longer publishes them clearly. Private data - which is what this app stores - counts against each user's own iCloud quota and costs the developer nothing. That part is documented by Apple.
- **Commission rates may move.** There is live litigation that could change App Store rates. 15% under the Small Business Program is what is documented today.
- **TestFlight builds expire after 90 days**, so a long beta needs re-uploads. Plan the beta as weeks, not months.
- **Review outcomes are never certain.** Section two reduces the risk. It cannot eliminate it.

SECTION TWELVE

The first three things

	Who	Action
1	You	Enrol in the Apple Developer Program on ONE Apple ID, and enrol in the Small Business Program in App Store Connect the same day. Reserve the app name while you are there. This also kills the 7-day expiry immediately.
2	Me	Rename the app to Do., then replace the web date input with a native picker. The name has to be right before any asset exists; the picker is the one visible flaw.
3	Both	Shoot the unfold once, roughly, on a phone, before any polish. If fifteen seconds of that does not make someone say 'wait, do that again', the positioning is wrong - and we would rather learn it in week one than week six.

The product is real, it runs, and the two things that make it unusual - the fold, and your whole day on one timeline - are already built and already verified on hardware. What stands between here and a listing is about three weeks of native surface, one very good fifteen second clip, and USD 99.

Prepared 9 November 2026, revised 10 November 2026 after the calendar and the lock-screen widgets shipped. Every task, meeting and name in the screenshots is invented. Figures marked unverified should be checked in App Store Connect before anything depends on them.
